Abstract

Complex RuCl₂(PPh₃)₂(*i*Bu-BTP) (**5**) was synthesized by the reaction of 2,6-bis(5,6-bis(*iso*-butyl)-1,2,4-triazin-3-yl)pyridine (*i*Bu-BTP) and RuCl₂(PPh₃)₃ in refluxing toluene, and its molecular structure was confirmed by X-ray crystallographic determination. Complex **5** was applied as a catalyst for transfer hydrogenation of ketones and exhibited catalytic activity comparable to RuCl₂(PPh₃)₂(Me₄BPPy) (**1**) (Me₄BPPy = bis(3,5-dimethylpyrazol-1-yl)pyridine) in some cases. The difference between the catalytic activity of **5** and **1** is attributed to the significantly different arrangement and positions of the PPh₃ and chlorides and also to the different electron density on the *N*-heterocycles. Complex **1** exhibited good to excellent catalytic activity in hydrogenation of ketones under mild conditions. These results have suggested new applications of *i*Bu-BTP and Me₄BPPy as promising planar tridentate *pseudo*-N₃ ligands to construct highly active transition-metal catalysts.

1. Introduction

Nitrogen-containing ligands have been extensively studied in coordination chemistry, and have been shown important applications in the fields of homogeneous catalysis and organic synthesis due to the easy manipulations and high reactivities of their transition metal complexes [1]. Recently, planar tridentate nitrogen donor (N₃) ligands 2,2':6',2''-terpyridines (**A**, terpy) [2], 2,6-bis(imino)pyridines (**B**) [3], and 2,6-bis(oxazolonyl)pyridines (**C**, Pybox) [4] (Chart 1) have been paid much attention. Non-planar *pseudo*-N₃ ligands hydridotris(pyrazol-1-yl)borates (**D**, Tp) have also been employed to build transition metal cat-

alysts [5]. Planar N₃ ligand 2,6-bis(5-methyl-1,2,4-triazol-3-yl)pyridine (**E**, BMTZP) was used to synthesize lanthanide complexes [6]. Very recently, bis(pyrazol-1-yl)pyridines (**F**) were reported to construct rare transition metal catalysts from our laboratories [7a,7b] and Karam's group [7c], respectively. In our previous communication [7b], complex RuCl₂(PPh₃)₂(Me₄BPPy) (**1**) (Me₄BPPy = a ligand of **F** type, i.e., bis(3,5-dimethylpyrazol-1-yl)pyridine) was synthesized and used as an efficient catalyst for transfer hydrogenation of ketones. Fe(II) and Co(II) complexes of ligands of type **F**, i.e., **F** · FeCl₂ and **F** · CoCl₂, were prepared and applied for ethylene polymerization [7c]. However, other types of N₃ and *pseudo*-N₃ ligands have seldom reported to construct late transition metal catalysts. Encouraged by the excellent catalytic activity of complex **1** in transfer hydrogenation of ketones [7b], we further investigated

61 2. Results and discussion

62 2.1. Synthesis and X-ray crystal structure of complex 5

63 Ligand 4 was prepared by means of a modified literature
 64 procedure (Chart 3) [6,8]. Condensation of pyridine-2,6-
 65 dicarbohydrazide imide (2) with 1,2-diketone (3) at heating
 66 afforded 2,6-bis(5,6-bis(*iso*-butyl)-1,2,4-triazin-3-yl)pyridine
 67 (*i*Bu-BTP) (4). Compound 4 is usually hydrated with
 68 one molecule of water after isolation from flash silica gel
 69 column chromatography. Although 4 is a *poly*-heterocyclic
 70 compound, it is bestowed with very good solubility in
 71 organic solvents including petroleum ether due to introduc-
 72 tion of four *iso*-butyl side chains to the two triazinyl rings.
 73 Reaction of ligand 4 with 1.0 equiv of $RuCl_2(PPh_3)_3$ [9] in
 74 refluxing toluene afforded complex $RuCl_2(PPh_3)_3(iBu-BTP)$
 75 (5) in 86% yield (Chart 3). Complex 5 is air- and moisture-
 76 stable and its single crystals suitable for X-ray crystallo-
 77 graphic study were obtained from recrystallization in
 78 CH_2Cl_2 /hexane (v/v, 1/4) at -20 °C. The NMR spectra
 79 of 5 reveals 4 to be a coordinating ligand in 5. The chemical
 80 shifts of the pyridyl CH hydrogen atoms in complex 5 are

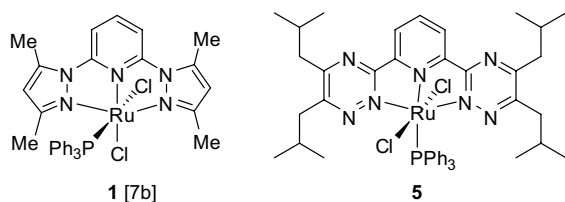

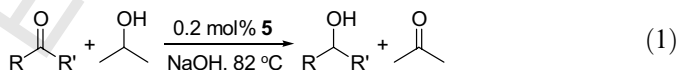

Chart 2. Ru(II) complexes 1 and 5.

81 shifted upfield by 0.2–0.3 ppm in the proton NMR spec-
 82 trum as compared with those of the free ligand 4.

83 In the solid state, complex 5 exhibits a neutral molecular
 84 structure in which 4 acts as a planar *pseudo*- N_3 ligand, and
 85 the metal center is six-coordinated with the tridentate
 86 *pseudo*- N_3 ligand, two chlorides, and one PPh_3 ligand
 87 (Fig. 1). The three Ru–N, two Ru–Cl and Ru–P bond dis-
 88 tances are 1.982(3), 2.032(3), 2.058(3), 2.3919(13),
 89 2.4110(13), and 2.3631(11) Å, respectively (Table 2). The
 90 Ru–N bond distances in 5 are very close to their analogues
 91 in 1 [7b], but the Ru–Cl and Ru–P bonds in 5 are shorter
 92 than those in 1. The significant structural difference
 93 between complexes 5 and 1 is that the two chlorides in 5
 94 are closely linear to each other (Cl(1)–Ru–Cl(2),
 95 $174.91(3)^\circ$) and positioned on the two sides of the *pseudo*-
 96 N_3 ligand plane, while the two chloride atoms in 1 are
 97 nearly perpendicular to each other. The pyridyl nitrogen
 98 atom is positioned *trans* to the PPh_3 ligand in 5 (N(1)–
 99 Ru–P, $175.80(8)^\circ$) (Fig. 1), while the PPh_3 ligand in 1 is
 100 arranged *trans* to one chloride and they are situated on
 101 the two sides of the ligand plane, respectively [7b]. The
 102 molecular structure of 5 demonstrates a rare example of
 103 transition metal complexes of a new pyridyl-based
 104 *pseudo*- N_3 ligand which has been structurally
 105 characterized.

61 2. Results and discussion

62 2.1. Synthesis and X-ray crystal structure of complex 5

62 2.2. Transfer hydrogenation of ketones catalyzed by complex 5

111 Ruthenium(II) complexes have been used as the most
 112 potential catalysts for transfer hydrogenation of ketones

113 [10] and are also becoming very promising catalysts for
 114 hydrogenation of ketones [11,12]. Complex 1 has showed
 115 excellent catalytic activity to transfer hydrogenation of
 116 ketones in 2-propanol, achieving a final TOF value as high
 117 as 6000 h^{-1} [7b]. That is, 2 mmol of acetophenones were
 118 completely transformed to the corresponding alcohols
 119 within 5 min in refluxing 2-propanol using 0.2 mol% 1 as
 120 the catalyst and KOⁱPr as the base. In a similar fashion
 121 complex 5 was applied in the catalytic transfer hydrogenation
 122 of ketones (Table 3). Using 0.2 mol% 5 as the catalyst

with a molar ratio of 500/25/1 for ketone/base/catalyst, 123
 transfer hydrogenation of acetophenone was carried out 124
 in 2-propanol at 82 °C (Eq. 1). K₂CO₃, KOⁱPr, KOH, 125
 and NaOH were tested as the bases to optimize the reaction 126
 conditions. Over a period of 4 h, the corresponding alcohol 127
 product from acetophenone reached 98%, 96%, 97%, and 128
 46% yields by GC analysis in the reactions using NaOH, 129
 KOH, KOⁱPr, and K₂CO₃ as the base, respectively. Thus, 130
 NaOH was selected as the reaction promoter although 131
 both KOH and KOⁱPr also worked well as a base in the 132

138 reactions. Increasing the catalyst loading, the reaction was
 139 accelerated. For example, with 0.3 mol% **5**, acetophenone
 140 was reached a complete conversion to form the alcohol
 141 product within 2.5 h (Entry 2, Table 3). Because a compar-
 142 ison study was intended between complexes **5** and **1**,
 143 0.2 mol% catalyst loading was used in the typical reactions
 144 (Table 3).

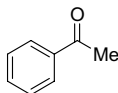

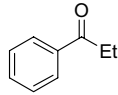

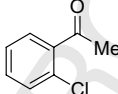

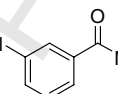

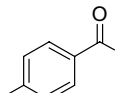

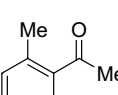

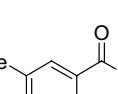

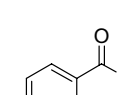

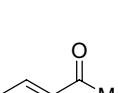

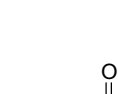

145 For most of the acetophenone substrates, their initial
 146 reaction rates were fast within the first 10 min within the
 147 first 10 min and then became smooth, or even very slow
 148 (Entries 1–11, Table 3). For example, acetophenone,
 149 substituted chloroacetophenones, and *p*-methylacetophe-
 150 none reached 36–45%, 32–35%, and 31% conversions
 151 within the first 10 min (Entries 1, 2, 4–6, and 11, Table
 152 3). For propiophenone, its initial reaction rate was not fast,
 153 but its reaction proceeded at a very constant rate, achieving
 154 a complete conversion within 4 h (Entry 3, Table 3). Pyr-
 155 idyl ketones slowly underwent the reactions and could
 156 not reach a high conversion within 24 h (Entries 12–14,
 157 Table 3), neither did α -tetralone show a high reactivity
 158 (Entry 15, Table 3). Internal ketones, i.e., β -tetralone and
 159 3-heptanone hardly reacted over a period of 24 h (Entries
 160 16 and 22, Table 3). However, 1-indanone and 9-fluore-
 161 none reached >96% conversions within 9–24 h (Entries 17
 162 and 18, Table 3). Catalyst **5** exhibited excellent catalytic
 163 activity to cyclohexanone, cyclopentanone, and 2-hepta-
 164 none (Entries 19–21, Table 3). It should be noted that the
 165 catalytic activity of complex **5** is comparable to that of
 166 complex **1** in the reactions of propiophenone, 4-methoxy-
 167 acetophenone, 2-benzopyridine, α -tetralone, 1-indanone,
 168 9-fluorenone, and the aliphatic ketones (Entries 3, 11, 13,
 169 15, and 17–21) under the stated conditions, and in other
 170 cases complex **1** showed much higher catalytic activity than
 171 **5** [7b]. The difference between the catalytic activity of com-
 172 plexes **1** and **5** in transfer hydrogenation of ketones is pre-
 173 sumably attributed to the significantly different
 174 arrangements of the PPh₃ ligand and the two chloride
 175 atoms around the metal centers and also to the various
 176 electronic properties of the pyridyl-supported *N*-heterocy-
 177 cles. That pyrazolyls in **1** are stronger σ -donor ligands than
 178 1,2,4-triazin-3-yls in **5** may help to form a relatively elec-
 179 tron-rich ruthenium center, thus stabilizing the active cata-
 180 lytic species. These results suggest that the arrangement of
 181 the PPh₃ and chloride moieties in **1** may be more favorable
 182 to stabilize the active catalytic species.

186 2.3. Hydrogenation of ketones catalyzed by complex **1**

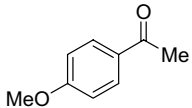

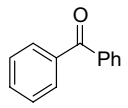

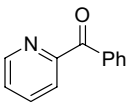

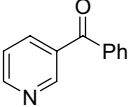

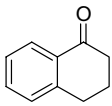

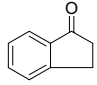

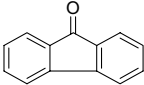

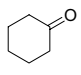

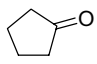

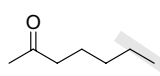

187 Complex **1** exhibited excellent catalytic activity for
 188 transfer hydrogenation of ketones [7b], which led us to
 189 investigate its catalytic activity for hydrogenation of
 190 ketones. It was found that complex **1** can also exhibit high
 191 catalytic activity in hydrogenation of ketones under mild

conditions (Eq. 2, Table 4). With a molar ratio of 500/20/1 for ketone/base/catalyst, the catalyst system with a combination of 2-propanol as the reaction medium and KO^tBu as the base promoter showed the best efficiency for hydrogenation of ketones. With 0.2 mol% **1** as the catalyst, hydrogenation of ketones was carried out in 2-propanol at 25 °C under a hydrogen atmosphere (20 atm). Over a period of 4 h, acetophenones and aliphatic ketones were reduced to the corresponding alcohols in excellent yields (Entries 1–11, 15, and 18–20). For benzophenone and 9-fluorenone, their corresponding alcohol products were formed in 83–92% yields (Entries 12 and 17, Table 4), while pyridyl ketones and 1-indanone were stubborn to be reduced under the stated conditions (Entries 13, 14, and 16, Table 4). It is noteworthy that by-products were not detected in the reaction mixtures. This protocol has demonstrated a promising catalyst system for hydrogenation of ketones under mild conditions.

Ruthenium hydride species generated from complexes **1** and **5** were presumably considered as the catalytically active species in transfer hydrogenation and hydrogenation of ketones. Thus, reduction of complexes **1** and **5** was carried out in methanol with NaBH₄ or dihydrogen under pressure and heating in order to isolate the ruthenium hydride complexes. Unfortunately, no success has been achieved. Ligands **4** and Me₄BPPy did not react with RuH(Cl)(PPh₃)₃ in CH₂Cl₂ or toluene at ambient temperature or heating to form the desired complexes RuH(Cl)(L)(PPh₃) which might be generated *in situ* to promote the catalytic transfer hydrogenation and hydrogenation of ketones. For the present transfer hydrogenation of ketones catalyzed by complex **5**, no obvious reaction undergo at ambient temperature in most cases, suggesting that heating is necessary to promote formation of the catalytically active species. In the hydrogenation of ketones using complex **1** as the catalyst, the reaction was negligible under a nitrogen atmosphere without dihydrogen, indicating that dihydrogen under pressure was involved in the reaction to promote formation of the catalytically active species at ambient temperature.

3. Summary

In summary, complex RuCl₂(PPh₃)(*i*Bu-BTP) (**5**) has exhibited moderate to good and excellent catalytic efficiency in the transfer hydrogenation of ketones, and its catalytic activity is comparable to that of complex RuCl₂(PPh₃)(Me₄BPPy) (**1**) in some cases. In most cases, complex **5** showed lower catalytic activity than **1**, which is presumably attributed to the significant structural difference between **5** and **1** and also to the various electronic properties of the pyridyl-supported *N*-heterocyclic rings. That the PPh₃ ligand and one chloride are linearly arranged and positioned on the two sides of the *pseudo*-N₃ ligand plane may lead to high catalytic activity for complexes of type RuCl₂(PPh₃)L (L = a planar tridentate ligand). The structural confirmation of complex **5** by X-

ray crystallography and its catalytic activity have revealed promising applications of the new family of planar tridentate *pseudo*-N₃ ligands, i.e., 2,6-bis(1,2,4-triazin-3-yl)pyridines, in transition metal-promoted catalysis. Complex RuCl₂(PPh₃)(Me₄BPPy) (**1**) exhibited good to excellent catalytic activity in hydrogenation of ketones under relatively mild conditions, suggesting that Me₄BPPy is a promising planar tridentate *pseudo*-N₃ ligand to construct highly active transition-metal catalysts.

4. Experimental section

4.1. General considerations

All the reactions were carried out under a nitrogen atmosphere with a drybox and standard Schlenk techniques. ¹H and ¹³C{¹H} NMR spectra were recorded on a 400 MHz spectrometer. Chemicals were used as received.

4.2. Preparation of the ligand *i*Bu-BTP (**4**)

Under nitrogen atmosphere, a mixture of pyridine-2,6-dicarbohydrazide imide **2** (9.66 g, 50 mmol) and 1,2-diketone **3** (17.02 g, 100 mmol) was stirred at 160 °C for 7 h. After cooled to ambient temperature, the resultant residue was purified by flash silica gel column chromatography with petroleum ether (30–60 °C) as the eluent. Further recrystallization from petroleum ether (30–60 °C) at –20 °C afforded yellow crystalline solid **4** (11.00 g, 45.9%). M.p.: 61–63 °C. ¹H NMR (CDCl₃, 400 MHz): δ 8.73 (d, *J* = 5.82 Hz, 2H) and 8.10 (t, 1H) (pyridyl CH), 3.55 (br, 2H, H₂O), 2.96 (d, 4H, *J* = 5.37 Hz, 2 × CH₂), 2.83 (d, 4H, *J* = 5.31 Hz, 2 × CH₂), 2.43 and 2.29 (m each, 2:2H, 4 × CH), 1.03 (d, *J* = 4.89 Hz, 4 × CH₃), 1.01 (d, *J* = 4.92 Hz, 4 × CH₃). ¹³C{¹H} NMR (CDCl₃): δ 161.75, 161.09, 159.63, and 154.07 (Cq each, C–N), 138.16 and 125.16 (1:2, aromatic CH), 42.49 and 41.25 (2:2, 4 × CH₂), 28.53 and 28.04 (2:2, 4 × CH), 22.77 and 22.63 (4:4, 8 × CH₃). Anal. Calc. for C₂₇H₃₉N₇ · H₂O: C, 67.61; H, 8.62; N, 20.44. Found: C, 67.64; H, 8.51; N, 20.95%.

4.3. Preparation of complex RuCl₂(PPh₃) (*i*Bu-BTP) (**5**)

A mixture of ligand *i*Bu-BTP **4** (0.498 g, 1.0 mmol), RuCl₂(PPh₃)₃ (0.995 g, 1.0 mmol) in 60 mL of refluxing toluene was stirred until all the ligand was consumed over a period of ca 3 h. The reaction mixture was cooled to ambient temperature, and all the volatiles were removed under reduced pressure, affording a purple residue. The resultant residue was washed with hexane (10 × 2 mL) until no free ligand was detected from the filtrate by TLC analysis. The resultant material was dissolved in 40 mL toluene at 50 °C and then cooled to ambient temperature. Recrystallization at –20 °C overnight afforded purple crystals. The mother liquor was concentrated under reduced pressure and then subject to flash silica gel column chromatography (diethyl ether/petroleum (30–60 °C), 10/1). Combined the

purple solid, a total of 0.80 g (86.0%) **5** was obtained. The single crystals suitable for X-ray crystallographic study were grown in CH₂Cl₂/hexane (v/v, 1/4) at –20 °C. M.p.: 232 °C. ¹H NMR (CDCl₃, 400 MHz): δ 8.42 (d, 2H), 7.90 (m, 7H) and 7.27 (m, 9H) (pyridyl and phenyl CH), 2.70 (d, *J* = 5.16 Hz, 4H, 2 × CH₂), 2.41 (d, *J* = 5.37 Hz, 4H, 2 × CH₂), 2.35 and 1.63 (m each, 2:2H, 4 × CH), 1.06 and 0.79 (d each, *J* = 4.95 Hz, 12:12H, 8 × CH₃). ¹³C{¹H} NMR (CDCl₃): δ 164.72, 159.88, 158.13 and 155.76 (Cq each, C–N), 136.26 (Cq, *i*-C of Ph), 135.87, 135.31, 135.22, 128.53, 127.10, 127.02, and 124.41 (pyridyl and phenyl CH), 41.98 and 40.95 (2:2, 4 × CH₂), 27.64 and 27.52 (2:2, 4 × CH), 22.88 (8 × CH₃). Anal. Calc. for C₄₅H₅₄C₁₂N₇PRu: C, 59.96; H, 6.10; N, 10.80. Found: C, 60.33; H, 6.08; N, 10.94%.

4.4. General procedure for transfer hydrogenation of ketones catalyzed by **5**

Under nitrogen atmosphere, a mixture of ketone (2 mmol), catalyst **5** (3.6 mg, 0.004 mmol), and 2-propanol (19 mL) was stirred at 82 °C for 10 min. 1.0 mL of 0.1 M NaOH solution in 2-propanol was then introduced. The reaction mixture was stirred at the refluxing temperature and samples were taken for GC analysis at 10 min, 1 h, 1.5 h, 2.0 h, 2.5 h, 3.0 h, 3.5 h, 4.0 h, 4.5 h, 5.0 h, 24 h, etc. After the reaction was finished, the mixture was condensed under reduced pressure and subject to flash silica gel column chromatography to afford the alcohol product. Acetone and the corresponding alcohols were detected as the products in all the cases. The alcohol products were identified by comparison with the authentic samples and/or by proton NMR measurements.

4.5. Typical procedure for hydrogenation of ketones catalyzed by **1**

Under nitrogen atmosphere, complex **1** (2.0 mg, 0.003 mmol), KO^tBu (3.4 mg, 0.03 mmol) and 1 mL of 2-propanol were successively added to a 10-mL vial, and the mixture was stirred at ambient temperature for 5 min. A ketone (1.5 mmol) in 2 mL 2-propanol were added, and the vial was placed in a 200-mL autoclave, and then the autoclave atmosphere was replaced with hydrogen for three times, pressured H₂ to the stated pressure to start the reaction with stirring. After the reaction was finished, the reaction mixture was analyzed or condensed for isolation of the product in the above mentioned procedures.

4.6. X-ray crystallographic studies

Single crystal X-ray diffraction studies for complex **5** was carried out on a SMART APEX diffractometer with graphite-monochromated Mo K α radiation (λ = 0.71073 Å). Cell parameters were obtained by global refinement of the positions of all collected reflections. Intensities were corrected for Lorentz and polarization

348 effects and empirical absorption. The structures were
349 solved by direct methods and refined by full-matrix least
350 squares on F^2 . All non-hydrogen atoms were refined aniso-
351 tropically. All hydrogen atoms were placed in calculated
352 positions. Structure solution and refinement were per-
353 formed by using the SHELXL-97 package. Crystal data and
354 refinement details for these complex **5** are summarized in
355 Table 1.

356 Acknowledgements
